SYSTEM DESIGN DOCUMENT

AI Tax System

AI tax return processing for CPA firms - OCR + Claude + ProConnect / DrakeTax export

PREPARED FOR

CPA firms evaluating AI document pipelines

Tax Workflow Automation — System Design

Prepared for	CPA firm (Upwork, 2026-04-18)
Prepared by	Vitalijus Alsauskas · Hyperion AI
Scope	AI-driven tax return processing — OCR + Claude extraction + ProConnect / DrakeTax export

1. Problem Framing

The hard part isn't the LLM call — it's keeping accuracy consistent across document variants and making sure PII never leaks.

Naive AI tax pipelines fail in predictable ways:

- **Messy document variants** — scanned 1099s, prior-year returns with handwritten notes, K-1s with non-standard layouts
- **Silent hallucinations** — the model returns a plausible number that's wrong, it ships to ProConnect, the CPA catches it weeks later
- **PII leaks** — SSNs and ITINs land in LLM provider logs that shouldn't have them

This design makes all three **impossible by construction**: OCR-first reduces hallucination surface, per-field confidence gates route uncertain data to human review, and prompt-level PII redaction keeps sensitive data out of the model provider entirely.

---

2. System Diagram

Every extracted field carries a **confidence score**. High-confidence fields flow straight to mapping. Anything below threshold drops into a **human review queue** before it ever reaches ProConnect or DrakeTax.

3. Tool Choices

LAYER	PICK	WHY THIS	ALTERNATIVES CONSIDERED
Upload UI	Next.js 15 (App Router)	Server Components keep PII off the client, signed upload URLs	Plain React SPA (leaks more data to browser), Streamlit (not production-ready for firm use)
Encrypted storage	AWS S3 with SSE-KMS + signed URLs	Managed encryption, audit events via CloudTrail, data residency options	Supabase Storage (fine, fewer compliance controls), Azure Blob (works if you're in Azure already)
OCR	AWS Textract	Best-in-class on tables, 1099s, scanned returns	Google Vision (close, weaker on tabular data), Tesseract (free, worse on messy scans)
LLM extraction	Claude 3.5 Sonnet (Anthropic API, zero-retention)	Strongest structured extraction, supports JSON mode, zero-retention PII handling	GPT-4o (very close, retention defaults less favorable), local Llama (cheaper but unreliable on financial docs)
Confidence scoring	LLM self-score + regex validation	Cheap, interpretable, catches most hallucinations	Fine-tuned classifier (overkill for volume you're at)
Review queue	Postgres table + Next.js admin UI	Simple, auditable, CPAs already work in browser	Airtable (not HIPAA-aligned), Retool (ongoing cost, vendor lock-in)
Mapping to ProConnect / DrakeTax	Python mapper module per target	Each tax software has quirks, keeping them isolated avoids cross-contamination	Single unified schema (brittle when target changes)
Observability	Sentry + structured logs in S3	Incidents caught fast, immutable audit log for compliance	DataDog (overpriced for a firm), CloudWatch (weak UX)

4. Data Flow

Happy path (~80% of returns)

1. **Upload** — CPA uploads via signed URL; file lands in encrypted S3, audit log entry written
2. **OCR** — worker picks up file, runs Textract, stores raw text + layout metadata
3. **Extract** — Claude returns structured fields with per-value confidence scores
4. **Gate** — fields ≥ threshold flow straight to mapping; below threshold enter review
5. **Map** — Python mapper produces ProConnect- or DrakeTax-ready record
6. **Deliver** — CPA downloads the mapped output when ready

Low-confidence path (~15-20% of returns)

- Any field below threshold (e.g. **< 0.85 on a $ value**) drops into the review queue
- CPA opens the Review UI with original document region next to extracted value
- CPA corrects or approves; fix logged against field for future prompt tuning
- Only **after human approval** does the field flow to mapping

Error paths

FAILURE	HANDLING
OCR fails / returns garbage	Return flagged `unprocessable`, routed to manual-entry queue
LLM timeout or rate limit	Exponential backoff; fallback to secondary model after 3 failures
S3 upload fails	Clear error to user; nothing partial stored
Mapping layer rejects a field	Blocks export; surfaces structured error with "fix field" link
PII leak risk	Prompts redacted (SSN/ITIN → tokens); any unredactable prompt skips LLM entirely, field goes straight to manual review

5. Component Breakdown

COMPONENT	STACK	RESPONSIBILITY
Ingest Service	FastAPI + signed S3 URLs	Uploads, validation, encryption at rest, audit logging. Nothing touches the LLM here.
OCR Worker	Celery + AWS Textract	Pulls from S3, parses to text + layout, writes to processing bucket.
Extraction Worker	Celery + Anthropic SDK	Claude extracts 30-50 fields with JSON output + confidence scores.
Review UI	Next.js route `/review`	Low-confidence field inspector, inline corrections, audit trail per edit.
Mapping Layer	`proconnect.py`, `draketax.py`	One module per target isolates format quirks so one doesn't break the other.
Export Service	FastAPI endpoint	Generates final file in target format when CPA marks return ready.
Audit & Observability	Sentry + structured logs + immutable S3	Every action logged, every mutation traceable, breach response ready.

6. Implementation Phases

PHASE	WEEKS	SHIPS	KEY MILESTONES
1. Foundation	1-2	End-to-end skeleton for one document type (1099-MISC)	Upload portal, Textract wired up, Claude extracts ~10 fields, basic review UI, deployment pipeline to staging
2. Coverage	3-4	Full field coverage for 5 most common forms	1040, 1099s (MISC/NEC/INT/DIV), K-1, W-2, Schedule C; ProConnect mapper; polished review UI; load tested at season volume
3. Production	5-6	Second target + observability + handoff	DrakeTax mapper; Sentry→Slack alerts; oncall runbook; knowledge transfer session + recorded walkthrough

7. Risks & Mitigations

#	RISK	MITIGATION
1	**Claude hallucinates values** on messy scans, wrong numbers reach ProConnect	Confidence scoring + review queue. Nothing exports without high model confidence OR human approval. Auto-approved fields still logged with source coordinates for retroactive audit.
2	**PII leaks** through LLM prompts or provider retention	Anthropic zero-retention flag on. SSN/ITIN redacted before prompts (reversible tokens). Audit log of every prompt. Data never leaves your AWS account except the scrubbed LLM call.
3	**Tax-season volume spike** breaks the pipeline	Celery autoscales on queue depth. Depth alerts at 100. Fallback to Claude Haiku under extreme load so nothing stalls. Load tested at 3× season volume.
4	**ProConnect / DrakeTax** changes import format mid-season	Mapping layer isolated per target — one format change doesn't break the other. Nightly integration tests against sample imports alert on regressions.
5	**CPA correction corrupts historical data**	All corrections append-only. Every correction carries user ID + timestamp. Original extraction preserved. Bad corrections replayable from audit log.

8. What I Need From You

To move into Phase 1, a few inputs from your side:

- **5-10 real returns** (redacted is fine) — calibrates extraction accuracy on your actual document mix, not synthetic data
- **Test ProConnect or DrakeTax account** — for the mapping layer
- **Field priorities** — which 20-30 fields are must-haves vs. nice-to-haves (I can send a suggested list)
- **Data residency confirmation** — US-only, or flexible?
- **30-minute kickoff call** — to walk this through and tighten scope before any code ships

---

This document is yours to keep regardless of whether we end up working together. If you hire someone else to build this, the architecture and tool choices here should still save them two weeks of thinking.
